Linear Programming

1.1 Linear Programming

Recall that in general, an optimisation problem can be formulated as

$$\min_{\mathbf{x} \in \mathbb{R}^n} f(\mathbf{x})$$

s.t. $\mathbf{x} \in P$,

where $P \subseteq \mathbb{R}^n$ is called the *feasible set* (or *feasible region*).

Definition 1.1.1 ► Linear Programming Problem

A linear programming (LP) problem is an optimisation problem where the objective function f is linear and the feasible set P is a polyhedron.

We can therefore formulate a linear programming problem as

$$\min_{\boldsymbol{x} \in \mathbb{R}^n} \boldsymbol{c}^{\mathrm{T}} \boldsymbol{x}$$
s.t. $\boldsymbol{a}_i^{\mathrm{T}} \boldsymbol{x} \leq b_i$ for $i = 1, 2, \dots, p$

$$\boldsymbol{a}_j^{\mathrm{T}} \boldsymbol{x} = b_j$$
 for $i = 1, 2, \dots, m$,

where $c \in \mathbb{R}^n$ is called the *cost* or *profit* vector, $\mathbf{a}_i^T \mathbf{x}$ and $\mathbf{a}_j^T \mathbf{x}$ are called the *constraints* and \mathbf{x} is known as *decision variables*.

In particular, the following is known as the *standard form* of a linear program:

$$\min_{\boldsymbol{x} \in \mathbb{R}^n} \boldsymbol{c}^{\mathrm{T}} \boldsymbol{x}$$
s.t. $\boldsymbol{A} \boldsymbol{x} = \boldsymbol{b}$

$$x_i \ge 0, \quad \text{for } i = 1, 2, \dots, m.$$

One should realise that a linear program in the standard form can be more easily solved by using linear algebra to find the optimal solution. Note that not every optimisation problem is given in the standard form. Fortunately, we can always convert a linear program into the standard form.

For example, consider the constraint $a_i x_i \le b_i$. Notice that this is essentially equivalent to $a_i x_i + s_i = b_i$ for some $s_i \ge 0$ known as the *slack variable*. Similarly, $a_j x_j \ge b_j$ can be re-written as $a_i x_j - s_j = b_j$ for ome $s_j \ge 0$.

Note that some of the x_i 's may be free variables. In this case, we can convert it to $x_i^+ - x_i^-$ for some $x_i^+, x_i^- \ge 0$. For instance, we can take $x_i^+ = 0$ and $x_i^- > 0$ whenever $x_i < 0$ and vice versa for $x_i > 0$. Note that this correspondence is not unique.

1.2 Convex Sets and Functions

Proposition 1.2.1

Let $f_1, f_2, \dots, f_m : \mathbb{R}^n \to \mathbb{R}$ be convex functions, then the function

$$f(\mathbf{x}) \coloneqq \max_{i=1,2,\cdots,m} f_i(\mathbf{x})$$

is convex.

Proof. Take any $x \neq y \in \mathbb{R}^n$ and consider $\lambda x + (1 - \lambda)y$ for some $\lambda \in [0, 1]$. Note that for each of the f_i 's, we have

$$f_i(\lambda x + (1 - \lambda)y) \le \lambda f_i(x) + (1 - \lambda)f_i(y),$$

and so

$$\max_{i=1,2,\cdots,m} f_i(\lambda \mathbf{x} + (1-\lambda)\mathbf{y}) \le \max_{i=1,2,\cdots,m} [\lambda f_i(\mathbf{x}) + (1-\lambda)f_i(\mathbf{y})].$$

Therefore,

$$f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) = \max_{i=1,2,\cdots,m} f_i(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y})$$

$$\leq \max_{i=1,2,\cdots,m} [\lambda f_i(\mathbf{x}) + (1 - \lambda)f_i(\mathbf{y})]$$

$$= \lambda \max_{i=1,2,\cdots,m} f_i(\mathbf{x}) + (1 - \lambda) \max_{i=1,2,\cdots,m} f_i(\mathbf{y})$$

$$= \lambda f(\mathbf{x}) + (1 + \lambda)f(\mathbf{y}).$$

1.3 Geometry of Linear Programming

Definition 1.3.1 ▶ Polyhedron

A polyhedron is defined as the set

$$P \coloneqq \{ \boldsymbol{x} \in \mathbb{R}^n : \boldsymbol{A}\boldsymbol{x} \le \boldsymbol{b} \}$$

where $\mathbf{A} \in \mathbb{R}^{m \times n}$ and $\mathbf{b} \in \mathbb{R}^m$.

Geometrically, a polyhedral set P can be defined alternatively as a finite intersection of half-planes:

$$P \coloneqq \bigcap_{i=1}^m \left\{ \boldsymbol{x} \in \mathbb{R}^n : \, \boldsymbol{a}_i^{\mathrm{T}} \boldsymbol{x} \le b_i \right\}.$$

Theorem 1.3.2 ▶ Basic Solution Characterisation

A vector $\mathbf{x}^* \in \mathbb{R}^n$ is a basic solution if and only if

- $Ax^* = b$, and
- There exists an index set $B \subseteq \{1, 2, \dots, n\}$ such that the set

$$\{A_i: i \in B\}$$

is linearly independent and $x_j^* = 0$ for all $j \notin B$.

Theorem 1.3.3 ▶ Equivalent Conditions for the Existence of Basic Feasible Solution

Let $\mathbf{A} \in \mathbb{R}^{m \times n}$ where $m \ge n$ and

$$P = \{ \boldsymbol{x} \in \mathbb{R}^n : A\boldsymbol{x} \geq \boldsymbol{b} \} \neq \emptyset.$$

The following statements are equivalent:

- 1. P does not contain any straight line.
- 2. P has a basic feasible solution.
- 3. P has n linearly independent constraints.
